

A NON-COMMUTATIVE BGG CORRESPONDENCE

PETER JØRGENSEN

ABSTRACT. A non-commutative version of the Bernstein-Gel'fand-Gel'fand (BGG) correspondence is set up, and a sample application is given to periodic injective resolutions.

0. INTRODUCTION

The Bernstein-Gel'fand-Gel'fand correspondence is surprising. It gives an equivalence of categories

$$\overline{\mathrm{gr}}(E) \simeq \mathrm{D}^b(\mathrm{coh} \mathbb{P}^{d-1}).$$

This was proved in [4, thm. 2] and as always, to explain such a formula requires lots of words. On the left hand side, E is the exterior algebra $\bigwedge(Y_1, \dots, Y_d)$ and $\overline{\mathrm{gr}}(E)$ is the category of finitely generated graded E -left-modules modulo morphisms which factor through injectives.

On the right hand side, $\mathbb{P}^{d-1}$ is $(d-1)$ -dimensional projective space, $\mathrm{coh} \mathbb{P}^{d-1}$ is the category of coherent sheaves on $\mathbb{P}^{d-1}$, and $\mathrm{D}^b(\mathrm{coh} \mathbb{P}^{d-1})$ is the derived category of bounded complexes of such sheaves. The surprising thing about the Bernstein-Gel'fand-Gel'fand (BGG) correspondence is that the geometric object on the right hand side is equivalent to the purely algebraic object on the left hand side.

Put differently, if one did not know about the BGG correspondence, it would really not be obvious that it is possible to recover $\mathrm{D}^b(\mathrm{coh} \mathbb{P}^{d-1})$ purely algebraically!

In this paper, I will generalize the BGG correspondence to non-commutative projective geometry. Non-commutative projective geometry is well established; one of the seminal papers is [1] but many have been published since, showing how a range of projective geometry can be generalized in a non-commutative way. This turns out also to be true of the BGG correspondence which is generalized in theorem 3.1 below, and now takes the form

$$\overline{\mathrm{Gr}}(A^!) \simeq \mathrm{D}(\mathrm{QGr} A).$$

2000 *Mathematics Subject Classification.* 14A22, 16E05, 16W50.

Key words and phrases. Bernstein-Gel'fand-Gel'fand correspondence, Frobenius algebra, periodic injective resolution.

Here A is a suitable non-commutative graded algebra with Koszul dual algebra $A^!$, and the category $\mathbf{QGr}(A)$ is a non-commutative analogue of the category $\mathbf{QCoh}(\mathbb{P}^{d-1})$ of quasi-coherent sheaves on $\mathbb{P}^{d-1}$.

After proving this, I consider a sample application to periodic injective resolutions. The background is Eisenbud's result [5, thm. 2.2]: Let M be a finitely generated graded module without injective direct summands over the exterior algebra E , for which the Bass numbers $\mu^i(M) = \dim_k \mathrm{Ext}_E^i(k, M)$ are bounded for $i \geq 0$. Then the minimal injective resolution I of M is periodic with period one: All the I^i and all the ∂_I^i are the same, up to isomorphism and degree shift. (In fact, Eisenbud worked with minimal free resolutions, but using the Matlis duality functor $\mathrm{Hom}_k(-, k)$ on his result gives the above.) In section 5, I start by showing that this phenomenon can be understood geometrically in a very simple way:

Using the BGG correspondence, the module M can be translated to a geometric object on $\mathbb{P}^{d-1}$. Since the Bass numbers of M are bounded, this object turns out to have zero dimensional support, so is stable under twisting, that is, tensoring by $\mathcal{O}_{\mathbb{P}^{d-1}}(1)$. Translating back, this means that M is its own first syzygy, and periodicity of the minimal injective resolution follows.

Next in section 5, I consider the non-commutative case where a similar procedure yields remarkably different results: Let A be a suitable non-commutative graded algebra, and let M be a finitely generated graded module over the Koszul dual $A^!$, for which the Bass numbers $\mu^i(M)$ are bounded for $i \geq 0$. Then, choosing A and M prudently, it is possible to make the minimal injective resolution of M periodic with any finite period, or to make it aperiodic.

The reason is that when translating M through the non-commutative BGG correspondence, one still obtains a geometric object with zero dimensional support. However, due to the non-commutative (hence non-local) nature of the situation, it is no longer true that such an object is invariant under twisting. Rather, the object can have orbit of any finite length, or have infinite orbit. Translating back gives the above results on periodicity of the minimal injective resolution.

Note that the concrete example I will give of this behaviour is already known from [10]. But the present geometric view through the BGG correspondence is new.

After these remarks, let me end the introduction with a synopsis of the paper. Section 1 exhibits $\mathbf{D}(\mathbf{QGr} A)$ as a full subcategory of $\mathbf{D}(\mathbf{Gr} A)$. Section 2 considers a version of Koszul duality. Section 3 combines these results into the non-commutative BGG correspondence,

and shows that under the correspondence, the simple module k over $A^!$ corresponds to the “structure sheaf” $\mathcal{O}$ in $\mathbf{D}(\mathbf{QGr} A)$.

Section 4 does a few computations which are put to use in section 5, where the BGG correspondence is applied to periodicity of minimal injective resolutions.

To avoid a lengthy section on nomenclature, hints on notation are given along the way. The reader should rest assured that no new, let alone revolutionary, notation is introduced. The paper remains firmly on classical ground, and differs notationally only in minor details from such papers as [1], [9], and [10]. However, I do need to perform the following blanket setup which applies throughout.

Setup 0.1. k is a field, and $A = k \oplus A_1 \oplus A_2 \oplus \cdots$ is a connected $\mathbb{N}$ -graded noetherian k -algebra which is AS regular and Koszul (see [9, p. 206] and [2, def. 1.2.1], or remark 0.2). I assume $\text{gldim } A = d \geq 2$.

By [2, cor. 2.3.3], the algebra A is quadratic, that is, it has the form

$$A \cong T(V)/(R)$$

where V is a finite dimensional vector space, $T(V)$ the tensor algebra, and (R) the two sided ideal generated by a space of relations R in $V \otimes_k V$. Let $(-)'$ denote $\text{Hom}_k(-, k)$ and define $R^\perp$ by the exact sequence

$$0 \rightarrow R^\perp \longrightarrow V' \otimes_k V' \longrightarrow R' \rightarrow 0.$$

Then the Koszul dual algebra of A is

$$A^! = T(V')/(R^\perp),$$

see [2, dfn. 2.8.1].

Remark 0.2. (i) For A to be AS regular means that $\text{gldim } A = d$ is finite, and that the graded A -bi-module $k = A/A_{\geq 1}$ satisfies

$$\text{Ext}_A^i(k, A) \cong \text{Ext}_{A^{\text{op}}}^i(k, A) \cong \begin{cases} 0 & \text{for } i \neq d, \\ k(\ell) & \text{for } i = d \end{cases}$$

for some ℓ . As usual, $(-)(\ell)$ denotes ℓ 'th degree shift of graded modules, so $M(\ell)_i = M_{i+\ell}$.

(ii) For A to be Koszul means that the minimal free resolution L of the graded A -left-module $k = A/A_{\geq 1}$ is linear. That is, the i 'th module L_i has all its generators in graded degree i , so has the form $\coprod A(-i)$.

(iii) It is easy to see that since A is Koszul, the constant ℓ in (i) must be d .

(iv) By [2, thm. 2.10.1] there is the isomorphism $(A^!)^{\text{op}} \cong \text{Ext}_A(k, k)$. Combining this with $\text{gldim } A = d$ gives that $A^!$ is concentrated in graded degrees $0, \dots, d$.

(v) The algebra $A^!$ is graded Frobenius by [10, prop. 5.10]. This means that $\dim_k A^!$ is finite, and that there is an isomorphism of graded $A^!$ -left-modules $(A^!)' \cong A^!(m)$, where $(A^!)' = \operatorname{Hom}_k(A^!, k)$ is the Matlis dual module of $A^!$.

(vi) Since $A^!$ is concentrated in graded degrees $0, \dots, d$, the constant m in (v) must be d . So there is an isomorphism of graded $A^!$ -left-modules $(A^!)' \cong A^!(d)$.

1. THE CATEGORIES $\operatorname{Gr}(A)$ AND $\operatorname{QGr}(A)$

Remark 1.1. Let me first recapitulate a few items from [1], to which I refer for further details and proofs.

The category $\operatorname{Gr}(A)$ has as objects all $\mathbb{Z}$ -graded A -left-modules and as morphisms all homomorphisms of A -left-modules which preserve graded degree.

A module M in $\operatorname{Gr}(A)$ is called torsion if each m in M is annihilated by $A_{\geq n}$ for some n . The torsion modules form a dense subcategory $\operatorname{Tors}(A)$ of $\operatorname{Gr}(A)$, and the quotient category is

$$\operatorname{QGr}(A) = \operatorname{Gr}(A) / \operatorname{Tors}(A).$$

This category behaves like the category of quasi-coherent sheaves on the space $\operatorname{Proj}(A)$, although $\operatorname{Proj}(A)$ itself may not make sense. For instance, if A is commutative, then $\operatorname{QGr}(A)$ is in fact equivalent to the category of quasi-coherent sheaves on $\operatorname{Proj}(A)$ by Serre's theorem, as given in [1, thm., p. 229].

The degree shifting functor $(-)(1)$ on $\operatorname{Gr}(A)$ induces a functor on $\operatorname{QGr}(A)$ which I will also denote $(-)(1)$.

The category $\operatorname{Gr}(A)$ has the full subcategory $\operatorname{gr}(A)$ consisting of finitely generated modules. Induced by this, $\operatorname{QGr}(A)$ has the full subcategory $\operatorname{qgr}(A)$ which behaves like the category of coherent sheaves on $\operatorname{Proj}(A)$.

The projection functor $\operatorname{Gr}(A) \xrightarrow{\pi} \operatorname{QGr}(A)$ has a right-adjoint functor $\operatorname{QGr}(A) \xrightarrow{\omega} \operatorname{Gr}(A)$ by [1, p. 234], so there is an adjoint pair

$$\operatorname{Gr}(A) \begin{array}{c} \xrightarrow{\pi} \\ \xleftarrow{\omega} \end{array} \operatorname{QGr}(A).$$

As follows from [1, prop. 7.1], these functors send injective objects to injective objects, and restrict to a pair of quasi-inverse equivalences

$$\operatorname{Inj}_{\text{tf}}(A) \begin{array}{c} \xrightarrow{\pi} \\ \xleftarrow{\omega} \end{array} \operatorname{QInj}(A) \tag{1}$$

between the subcategory of torsion-free injective objects of $\operatorname{Gr}(A)$ and the subcategory of all injective objects of $\operatorname{QGr}(A)$.

Let me next turn to derived categories. The projection functor π is exact so extends to a triangulated functor $D(\text{Gr } A) \xrightarrow{\pi} D(\text{QGr } A)$ between derived categories. Moreover, since A has finite global dimension, each object of the category $\text{Gr}(A)$ has a bounded resolution by injective objects. The same therefore holds for $\text{QGr}(A)$, as one sees using ω and π . So right-derived functors can be defined on the unbounded derived categories $D(\text{Gr } A)$ and $D(\text{QGr } A)$ by [11, sec. 10.5].

In particular, $D(\text{QGr } A) \xrightarrow{R\omega} D(\text{Gr } A)$ exists, and it is not hard to see that

$$D(\text{Gr } A) \begin{array}{c} \xleftarrow{\pi} \\ \xrightarrow{R\omega} \end{array} D(\text{QGr } A) \quad (2)$$

is an adjoint pair of functors.

Definition 1.2. Let

$$k^\perp = \{ N \in D(\text{Gr } A) \mid \text{RHom}_A(k, N) = 0 \}.$$

Proposition 1.3. *The functors in equation (2) restrict to a pair of quasi-inverse equivalences of triangulated categories*

$$k^\perp \begin{array}{c} \xleftarrow{\pi} \\ \xrightarrow{R\omega} \end{array} D(\text{QGr } A). \quad (3)$$

Proof. First observe that diagram (1) extends to a pair of quasi-inverse equivalences

$$K(\text{Inj}_{\text{tf}} A) \begin{array}{c} \xleftarrow{\pi} \\ \xrightarrow{\omega} \end{array} K(\text{QInj } A) \quad (4)$$

between the homotopy category of complexes of torsion free injective objects of $\text{Gr}(A)$, and the homotopy category of complexes of injective objects of $\text{QGr}(A)$.

Next, finite global dimension of A implies that $D(\text{Gr } A)$ is equivalent to $K(\text{Inj } A)$, the homotopy category of complexes of injective objects of $\text{Gr}(A)$, and that under the equivalence, a right-derived functor RF on $D(\text{Gr } A)$ corresponds to the restriction of F to $K(\text{Inj } A)$. See e.g. [11, sec. 10.5]. A similar remark applies to $D(\text{QGr } A)$ and $K(\text{QInj } A)$. Therefore, up to equivalence, diagram (2) is

$$K(\text{Inj } A) \begin{array}{c} \xleftarrow{\pi} \\ \xrightarrow{\omega} \end{array} K(\text{QInj } A). \quad (5)$$

Translating diagram (4) through the equivalence between diagrams (5) and (2) shows that diagram (4) gives an equivalence between some subcategory of $D(\text{Gr } A)$, and the whole category $D(\text{QGr } A)$. To finish the proof, I must show that the subcategory in question is $k^\perp$. That is, I must show that the subcategory $K(\text{Inj}_{\text{tf}} A)$ of $K(\text{Inj } A)$ corresponds to the subcategory $k^\perp$ of $D(\text{Gr } A)$.

For this, note that by the above, the functor $\mathrm{Hom}_A(k, -)$ on $\mathbf{K}(\mathrm{Inj} A)$ corresponds to the derived functor $\mathrm{RHom}_A(k, -)$ on $\mathbf{D}(\mathrm{Gr} A)$, so I must show that $\mathbf{K}(\mathrm{Inj}_{\mathrm{tf}} A)$ is the subcategory of $\mathbf{K}(\mathrm{Inj} A)$ annihilated by $\mathrm{Hom}_A(k, -)$.

In fact, this is not quite true, but it is true and easy to see that the subcategory of $\mathbf{K}(\mathrm{Inj} A)$ annihilated by $\mathrm{Hom}_A(k, -)$ consists exactly of the complexes isomorphic to complexes in $\mathbf{K}(\mathrm{Inj}_{\mathrm{tf}} A)$, and this is enough. $\square$

2. KOSZUL DUALITY

Remark 2.1. Let me recapitulate one of the versions of Koszul duality set up in [6]. According to [6, thm. 7.2.3], there is a pair of quasi-inverse equivalences of triangulated categories

$$\mathbf{K}(\mathrm{CoFree} A^!) \xrightleftharpoons[\mathrm{G}]{\mathrm{F}} \mathbf{K}(\mathrm{Free} A). \quad (6)$$

Here $\mathrm{Free}(A)$ is the full subcategory of $\mathrm{Gr}(A)$ consisting of modules which have the form $\coprod_i A(n_i)$, and $\mathrm{CoFree}(A^!)$ is the full subcategory of $\mathrm{Gr}(A^!)$ consisting of modules which have the form $\prod_j (A^!)'(m_j)$. The categories $\mathbf{K}(\mathrm{CoFree} A^!)$ and $\mathbf{K}(\mathrm{Free} A)$ are the corresponding homotopy categories of complexes.

The functors F and G are constructed as follows in [6, sec. 3.2]. Given M in $\mathbf{K}(\mathrm{CoFree} A^!)$, one constructs a double complex

$$\begin{array}{ccccccc} & & \vdots & & \vdots & & \vdots \\ & & \uparrow & & \uparrow & & \uparrow \\ \cdots & \longrightarrow & A(1) \otimes M_1^{-1} & \longrightarrow & A(1) \otimes M_1^0 & \longrightarrow & A(1) \otimes M_1^1 \longrightarrow \cdots \\ & & \uparrow & & \uparrow & & \uparrow \\ \cdots & \longrightarrow & A \otimes M_0^{-1} & \longrightarrow & A \otimes M_0^0 & \longrightarrow & A \otimes M_0^1 \longrightarrow \cdots \\ & & \uparrow & & \uparrow & & \uparrow \\ \cdots & \longrightarrow & A(-1) \otimes M_{-1}^{-1} & \longrightarrow & A(-1) \otimes M_{-1}^0 & \longrightarrow & A(-1) \otimes M_{-1}^1 \longrightarrow \cdots \\ & & \uparrow & & \uparrow & & \uparrow \\ & & \vdots & & \vdots & & \vdots \end{array}$$

with certain differentials, and the total complex $\mathrm{Tot}^{\mathrm{II}}$, defined using coproducts, is $\mathrm{F}(M)$. In the diagram, superscripts indicate cohomological degree and subscripts indicate graded degree, so for instance, the

graded module in cohomological degree zero of the complex M is M^0 . Also, $\otimes$ indicates tensor product over k .

And given N in $\mathbf{K}(\text{Free } A)$, one constructs a double complex

$$\begin{array}{ccccccc}
 & & \vdots & & \vdots & & \vdots \\
 & & \uparrow & & \uparrow & & \uparrow \\
 \cdots & \longrightarrow & (A^!)'(1) \otimes N_1^{-1} & \longrightarrow & (A^!)'(1) \otimes N_1^0 & \longrightarrow & (A^!)'(1) \otimes N_1^1 \longrightarrow \cdots \\
 & & \uparrow & & \uparrow & & \uparrow \\
 \cdots & \longrightarrow & (A^!)' \otimes N_0^{-1} & \longrightarrow & (A^!)' \otimes N_0^0 & \longrightarrow & (A^!)' \otimes N_0^1 \longrightarrow \cdots \\
 & & \uparrow & & \uparrow & & \uparrow \\
 \cdots & \longrightarrow & (A^!)'(-1) \otimes N_{-1}^{-1} & \longrightarrow & (A^!)'(-1) \otimes N_{-1}^0 & \longrightarrow & (A^!)'(-1) \otimes N_{-1}^1 \longrightarrow \cdots \\
 & & \uparrow & & \uparrow & & \uparrow \\
 & & \vdots & & \vdots & & \vdots
 \end{array}$$

with certain differentials, and the total complex Tot^Π , defined using products, is $G(N)$.

Finite global dimension of A implies that $\mathbf{D}(\text{Gr } A)$ is equivalent to $\mathbf{K}(\text{Free } A)$ (see [11, sec. 10.5]), so the equivalences (6) can also be read as

$$\mathbf{K}(\text{CoFree } A^!) \begin{array}{c} \xrightarrow{F} \\ \xleftarrow{G} \end{array} \mathbf{D}(\text{Gr } A). \quad (7)$$

Remark 2.2. The name Koszul duality is potentially confusing since “duality” might lead one to think of contravariant functors, while F and G are in fact covariant.

For the following lemma, note that I use $\Sigma^i(-)$ for i ’th suspension, so if M is a complex then $(\Sigma^i M)^\ell = M^{i+\ell}$.

Lemma 2.3. *The functors F and G satisfy the following.*

- (i) $F(M(i)) \cong \Sigma^i(FM)(-i)$.
- (ii) $G(N(j)) \cong \Sigma^j(GN)(-j)$.
- (iii) $F((A^!)')$ is isomorphic to the A -left-module k , when both are viewed as objects of $\mathbf{D}(\text{Gr } A)$.

Proof. (i) and (ii) can be seen by playing with the double complexes which define F and G . (iii) holds by [6, exam. 3.1.1]. $\square$

Remark 2.4. The injective stable category over a ring is defined as the module category modulo the ideal of morphisms which factor through an injective module.

The present paper uses the graded version of this, so the injective stable category $\overline{\text{Gr}}(A^!)$ is defined as $\text{Gr}(A^!)$ modulo the ideal of morphisms which factor through an injective object of $\text{Gr}(A^!)$.

Since $A^!$ is graded Frobenius by remark 0.2(v), the category $\overline{\text{Gr}}(A^!)$ is triangulated. For M in $\overline{\text{Gr}}(A^!)$, the suspension ΣM is the first syzygy in an injective resolution of M . So ΣM is the cokernel of an injective pre-envelope, that is, an injective homomorphism $M \rightarrow I$ in $\text{Gr}(A^!)$ where I is an injective object of $\text{Gr}(A^!)$. Note that any injective pre-envelope can be used; changing the injective pre-envelope does not change the isomorphism class of ΣM in $\overline{\text{Gr}}(A^!)$.

The degree shifting functor $(-)(1)$ on $\text{Gr}(A^!)$ induces a functor on $\overline{\text{Gr}}(A^!)$ which I will also denote $(-)(1)$.

It is not hard to prove that $\overline{\text{Gr}}(A^!)$ is equivalent to the full subcategory of exact complexes in $\text{K}(\text{CoFree } A^!)$. Under the equivalence, a module M corresponds to a complete cofree resolution C of M , that is, a complex C in $\text{K}(\text{CoFree } A^!)$ which is exact and has zeroth cycle module $Z^0(C)$ isomorphic to M . To prove that this gives an equivalence, one uses that injective and projective objects of $\text{Gr}(A^!)$ coincide because $A^!$ is graded Frobenius; in particular, the objects of $\text{CoFree}(A^!)$ are both injective (since they are products of degree shifts of $(A^!)'$) and projective, and hence it is possible to construct complete cofree resolutions by splicing left-resolutions with right-resolutions.

Under the equivalence between $\overline{\text{Gr}}(A^!)$ and the full subcategory of exact complexes in $\text{K}(\text{CoFree } A^!)$, the suspension Σ on $\overline{\text{Gr}}(A^!)$ corresponds to the ordinary suspension Σ on $\text{K}(\text{CoFree } A^!)$, given by moving complexes one step to the left and switching signs of differentials. Also, the functor $(-)(1)$ on $\overline{\text{Gr}}(A^!)$ corresponds to the functor $(-)(1)$ on $\text{K}(\text{CoFree } A^!)$ induced by degree shifting of $A^!$ -left-modules.

Proposition 2.5. *The functors in equation (7) induce a pair of quasi-inverse equivalences of triangulated categories*

$$\overline{\text{Gr}}(A^!) \xrightleftharpoons{\quad} k^\perp.$$

Proof. Remark 2.4 identifies $\overline{\text{Gr}}(A^!)$ with the full subcategory of exact complexes in $\text{K}(\text{CoFree } A^!)$, and definition 1.2 defines $k^\perp$ as a full subcategory of $\text{D}(\text{Gr } A)$. To prove the proposition, I must show that these subcategories are mapped to each other by the functors F and G of equation (7).

However, let N be in $\mathbf{D}(\mathbf{Gr} A)$. Then the j 'th graded component of the i 'th cohomology module of the complex GN is

$$\begin{aligned} h^i(GN)_j &\stackrel{(a)}{\cong} \operatorname{Hom}_{\mathbf{K}(\mathbf{Gr} A^!)}(A^!, \Sigma^i(GN)(j)) \\ &\stackrel{(b)}{\cong} \operatorname{Hom}_{\mathbf{K}(\mathbf{CoFree} A^!)}((A^!)'(-d), \Sigma^i(GN)(j)) \\ &\cong (*), \end{aligned}$$

where (a) is classical and (b) holds because of $A^! \cong (A^!)'(-d)$, cf. remark 0.2(vi). Adjointness between F and G gives (c) in

$$\begin{aligned} (*) &\stackrel{(c)}{\cong} \operatorname{Hom}_{\mathbf{D}(\mathbf{Gr} A)}(F((A^!)'), \Sigma^i N(j+d)) \\ &\stackrel{(d)}{\cong} \operatorname{Hom}_{\mathbf{D}(\mathbf{Gr} A)}(k, \Sigma^i N(j+d)) \\ &\cong h^i \operatorname{RHom}_A(k, N)_{j+d}, \end{aligned}$$

and (d) is by lemma 2.3(iii).

But now it is clear that GN is exact if and only if N is in $k^\perp$, as desired. $\square$

3. THE BGG CORRESPONDENCE

Composing the equivalences of categories from propositions 1.3 and 2.5 gives the following main theorem of the paper.

Theorem 3.1 (The BGG correspondence). *There are quasi-inverse equivalences of triangulated categories*

$$\overline{\mathbf{Gr}}(A^!) \begin{array}{c} \xrightarrow{\varphi} \\ \xleftarrow{\gamma} \end{array} \mathbf{D}(\mathbf{QGr} A).$$

Example 3.2. If A is the polynomial algebra $k[X_1, \dots, X_d]$ then it is classical that A satisfies the conditions of setup 0.1, and the definition of $A^!$ in setup 0.1 makes it easy to see that $A^!$ is the exterior algebra $E = \bigwedge(Y_1, \dots, Y_d)$. Also, $\mathbf{QGr}(A)$ is equivalent to the category $\mathbf{QCoh}(\mathbb{P}^{d-1})$ of quasi-coherent sheaves on $(d-1)$ -dimensional projective space by Serre's theorem, [1, thm., p. 229]. So theorem 3.1 gives an equivalence of categories

$$\overline{\mathbf{Gr}}(E) \simeq \mathbf{D}(\mathbf{QCoh} \mathbb{P}^{d-1}).$$

This is the classical BGG correspondence, originally found in [4, thm. 2], with the slight improvement of dealing with the stable category of all modules and the unbounded derived category of quasi-coherent sheaves rather than the finite subcategories dealt with in [4, thm. 2].

Remark 3.3. The functors φ and γ from theorem 3.1 are constructed by composing the functors from propositions 1.3 and 2.5. Untangling this gives the following concrete descriptions of φ and γ .

To get $\varphi(M)$, first take a complete cofree resolution C of M and look at $F(C)$, where F is one of the functors from remark 2.1. Then $F(C)$ is in $\mathbf{K}(\mathbf{Free} A)$, and may also be viewed as being in $\mathbf{D}(\mathbf{Gr} A)$. Now $\varphi(M) = \pi F(C)$, where π is one of the functors from proposition 1.3.

To get $\gamma(\mathcal{M})$, first look at $R\omega(\mathcal{M})$ where $R\omega$ is one of the functors from proposition 1.3. Then $R\omega(\mathcal{M})$ is in $\mathbf{D}(\mathbf{Gr} A)$, and may also be viewed as being in $\mathbf{K}(\mathbf{Free} A)$. So $G(R\omega(\mathcal{M}))$ is in $\mathbf{K}(\mathbf{CoFree} A^!)$, where G is one of the functors from remark 2.1. In fact, $G(R\omega(\mathcal{M}))$ is even in the full subcategory of exact complexes in $\mathbf{K}(\mathbf{CoFree} A^!)$. Now $\gamma(\mathcal{M}) = Z^0 G(R\omega(\mathcal{M}))$, where Z^0 takes the zeroth cycle module.

The next lemma follows immediately from lemma 2.3, parts (i) and (ii).

Lemma 3.4. *The functors φ and γ satisfy the following.*

- (i) $\varphi(M(i)) \cong \Sigma^i(\varphi M)(-i)$.
- (ii) $\gamma(\mathcal{M}(j)) \cong \Sigma^j(\gamma \mathcal{M})(-j)$.

For the following lemma, let L be the minimal free resolution of the graded $A^!$ -left-module k . Each L^i is free and hence cofree because remark 0.2(vi) says $(A^!)^i \cong A^!(d)$. So L is a complex in $\mathbf{K}(\mathbf{CoFree} A^!)$, and I can apply the functor F from remark 2.1 and get a complex $F(L)$ in $\mathbf{D}(\mathbf{Gr} A)$.

Lemma 3.5. *The cohomology of $F(L)$ is torsion.*

Proof. By [6, sec. 3.2], the functor F exists in an alternative version, namely as a functor

$$\mathbf{Ch}(\mathbf{Gr} A^!) \xrightarrow{F} \mathbf{Ch}(\mathbf{Gr} A), \quad (8)$$

where $\mathbf{Ch}$ denotes categories whose objects are complexes and whose morphisms are chain maps. This alternative version of F induces the one from remark 2.1 because homotopy categories of complexes can be obtained from categories $\mathbf{Ch}$ by dividing away the ideals of null homotopic morphisms.

The version of F in equation (8) respects small colimits by [6, sec. 4.3]. In $\mathbf{Ch}(\mathbf{Gr} A^!)$ the object L is the colimit of the objects

$$L\langle j \rangle = \cdots \longrightarrow 0 \longrightarrow L^{-j} \longrightarrow \cdots \longrightarrow L^0 \longrightarrow 0 \longrightarrow \cdots,$$

so

$$F(L) \cong F(\operatorname{colim} L\langle j \rangle) \cong \operatorname{colim} F(L\langle j \rangle). \quad (9)$$

$$L^{-i} \cong \coprod A^!(-i). \quad (10)$$
$$\begin{array}{ccccccc}
& & A(d+j) \otimes L_{d+j}^{-j} & & & & \\
& & \uparrow & & & & \\
& & A(d+j-1) \otimes L_{d+j-1}^{-j} \longrightarrow \cdots & & & & \\
& & \uparrow & & & & \\
& & \vdots & \longrightarrow \cdots \longrightarrow \cdots \longrightarrow & A(d) \otimes L_d^0 & & \\
& & \uparrow & & & & \uparrow \\
& & A(j) \otimes L_j^{-j} \longrightarrow \cdots \longrightarrow \cdots \longrightarrow & \vdots & & & \\
& & & \uparrow & & & \\
& & & \cdots \longrightarrow A(1) \otimes L_1^0 & & & \\
& & & \uparrow & & & \\
& & & A \otimes L_0^0 & & &
\end{array} \tag{11}$$
$$\begin{array}{c} A \otimes (A^!)'_0 \\ \uparrow \\ \vdots \\ \uparrow \\ A(-d) \otimes (A^!)'_{-d}, \end{array}$$

and is a free resolution of the A -left-module k , as follows from [6, exam. 3.1.1]. So the columns of (11) have cohomology only at the top ends, and the cohomology in the $(-i)$ 'th column is $\coprod k(d+i)$.

Now consider the first spectral sequence of the double complex (11) (see [11, sec. 5.6]). The previous part of the proof shows that the E_2 -term of the spectral sequence is non-zero only at the top ends of the columns of (11), where

$$E_2^{0d} \cong \coprod k(d), \dots, E_2^{-j, d+j} \cong \coprod k(d+j).$$

Since the double complex is bounded in all directions, the spectral sequence converges towards the cohomology of Tot^{II} . Consequently, Tot^{II} of the double complex has cohomology only in cohomological degree d , and this cohomology sits in graded degrees $-d, \dots, -d-j$.

But this Tot^{II} is $F(L\langle j \rangle)$. So equation (9) now shows that $F(L)$ has cohomology only in cohomological degree d , and that this cohomology can be non-zero only in graded degrees $-d, -d-1, \dots$. In particular, the cohomology of $F(L)$ is torsion. $\square$

Now consider the graded A^1 -left-module k viewed as an object of $\overline{\text{Gr}}(A^1)$, and consider $\mathcal{O}$, the “structure sheaf” in $\text{QGr}(A)$ defined by $\mathcal{O} = \pi(A)$. Then $\mathcal{O}$ can also be viewed as a complex in $\text{D}(\text{QGr } A)$ concentrated in cohomological degree zero, and the following result holds.

Theorem 3.6. *The functor φ satisfies $\varphi(k) \cong \mathcal{O}$.*

Proof. To get $\varphi(k)$, I must take $\pi F(C)$, where C is a complete cofree resolution of the A^1 -left-module k , while π and F are the functors from proposition 1.3 and remark 2.1 (cf. remark 3.3).

Let L be a minimal free resolution of k , as in lemma 3.5. Also, consider the functor G from remark 2.1. From [6, exam. 3.1.1] follows that $G(A)$ is a cofree resolution of k . So there are canonical morphisms $L \rightarrow k$ and $k \rightarrow G(A)$ which compose to a morphism $L \rightarrow G(A)$ whose mapping cone C is easily seen to be a complete cofree resolution of k .

The distinguished triangle $L \rightarrow G(A) \rightarrow C \rightarrow$ in $\text{K}(\text{CoFree } A^1)$ gives a distinguished triangle

$$\pi F(L) \rightarrow \pi F G(A) \rightarrow \pi F(C) \rightarrow$$

in $\text{D}(\text{QGr } A)$. Let me compute the three complexes here: The cohomology of $F(L)$ is torsion by lemma 3.5, so $\pi F(L) \cong 0$. And F and G are quasi-inverse equivalences, so $F G(A)$ is isomorphic to A , so $\pi F G(A) \cong \pi(A) = \mathcal{O}$.

Finally, $\pi F(C)$ is $\varphi(k)$ as mentioned above. So the distinguished triangle reads

$$0 \rightarrow \mathcal{O} \rightarrow \varphi(k) \rightarrow,$$

proving $\varphi(k) \cong \mathcal{O}$. $\square$

4. COMPUTATIONS

This section contains computations, some involving the BGG correspondence, which will be used on periodic injective resolutions in section 5.

The following lemma is just a graded version of [3, cor. 2.5.4(ii)].

Lemma 4.1. *Let M be in $\overline{\text{Gr}}(A^!)$. There are canonical isomorphisms*

$$\text{Hom}_{\overline{\text{Gr}}(A^!)}(k, \Sigma^i M) \longrightarrow \text{Ext}_{\text{Gr}(A^!)}^i(k, M)$$

for $i \geq 1$.

Lemma 4.2. *Let M be in $\overline{\text{Gr}}(A^!)$ and consider $\mathcal{M} = \varphi(M)$ in $\text{D}(\text{QGr } A)$. Then*

$$\text{Ext}_{\text{Gr}(A^!)}^i(k, M(-i+j)) \cong \text{Ext}_{\text{QGr}(A)}^j(\mathcal{O}, \mathcal{M}(i-j))$$

for $i \geq 1$ and each j .

Proof. This is a simple computation:

$$\begin{aligned} \text{Ext}_{\text{Gr}(A^!)}^i(k, M(-i+j)) &\stackrel{(a)}{\cong} \text{Hom}_{\overline{\text{Gr}}(A^!)}(k, \Sigma^i M(-i+j)) \\ &\stackrel{(b)}{\cong} \text{Hom}_{\text{D}(\text{QGr } A)}(\varphi k, \varphi(\Sigma^i M(-i+j))) \\ &\stackrel{(c)}{\cong} \text{Hom}_{\text{D}(\text{QGr } A)}(\mathcal{O}, \Sigma^j \mathcal{M}(i+j)) \\ &= \text{Ext}_{\text{QGr}(A)}^j(\mathcal{O}, \mathcal{M}(i+j)), \end{aligned}$$

where (a) is by lemma 4.1 and (b) is by the BGG correspondence, theorem 3.1, while (c) is by theorem 3.6 and lemma 3.4(i). $\square$

For the following lemma, observe that the finitely generated graded modules form a full subcategory $\overline{\text{gr}}(A^!)$ of $\overline{\text{Gr}}(A^!)$, and that the complexes which have bounded cohomology consisting of objects from the category $\text{qgr}(A)$ form a full subcategory $\text{D}^b(\text{QGr } A)$ of $\text{D}(\text{QGr } A)$.

Lemma 4.3. *The subcategories $\overline{\text{gr}}(A^!)$ and $\text{D}^b(\text{QGr } A)$ map to each other under the BGG correspondence $\overline{\text{Gr}}(A^!) \xrightleftharpoons[\gamma]{\varphi} \text{D}(\text{QGr } A)$.*

Proof. It is not hard to check that $\overline{\text{gr}}(A^!)$ consists of the objects of $\overline{\text{Gr}}(A^!)$ which are finitely built from objects of the form $k(i)$.

Similarly, $\text{D}^b(\text{QGr } A)$ consists of the objects of $\text{D}(\text{QGr } A)$ which are finitely built from objects of the form $\mathcal{O}(j)$.

But under the BGG correspondence, $k(i)$ corresponds to $\Sigma^i \mathcal{O}(-i)$ by theorem 3.6 and lemma 3.4(i), so the present lemma follows. $\square$

Lemma 4.4. *Let $\mathcal{M}$ be in $D^b(\mathbf{QGr} A)$. Then for $i \gg 0$ I have*

$$\mathrm{Ext}_{\mathbf{QGr}(A)}^j(\mathcal{O}, \mathcal{M}(i-j)) \cong \mathrm{Hom}_{\mathbf{QGr}(A)}(\mathcal{O}, h^j(\mathcal{M})(i-j))$$

for each j , where $h^j(\mathcal{M})$ is the j 'th cohomology of $\mathcal{M}$.

Proof. The algebra A has global dimension d by assumption, so $\mathbf{qgr}(A)$ has cohomological dimension at most $d-1$ by [1, prop. 7.10(3)], so $\mathrm{Ext}_{\mathbf{QGr}(A)}^{\geq d}(\mathcal{O}, \mathcal{N}) = 0$ holds for each $\mathcal{N}$ in $\mathbf{qgr}(A)$.

Moreover, A is even AS regular by assumption, so $\mathbf{qgr}(A)$ satisfies Serre vanishing by [1, thms. 8.1(1) and 7.4]. That is, given $\mathcal{N}$ in $\mathbf{qgr}(A)$ and given p with $1 \leq p \leq d-1$, I have $\mathrm{Ext}_{\mathbf{QGr}(A)}^p(\mathcal{O}, \mathcal{N}(r)) = 0$ for $r \gg 0$.

Now, given $\mathcal{N}$, I can kill all the finitely many $\mathrm{Ext}_{\mathbf{QGr}(A)}^p(\mathcal{O}, \mathcal{N}(r))$ which might be non-zero by choosing r large enough. That is, given $\mathcal{N}$ in $\mathbf{qgr}(A)$, I have

$$\mathrm{Ext}_{\mathbf{QGr}(A)}^p(\mathcal{O}, \mathcal{N}(r)) = 0 \text{ for } r \gg 0 \text{ and each } p \geq 1. \quad (12)$$

There is a convergent spectral sequence

$$E_2^{pq} = \mathrm{Ext}_{\mathbf{QGr}(A)}^p(\mathcal{O}, h^q(\mathcal{M})(i-j)) \Rightarrow \mathrm{Ext}_{\mathbf{QGr}(A)}^{p+q}(\mathcal{O}, \mathcal{M}(i-j))$$

by [11, 5.7.9] (convergence because the cohomology $h(\mathcal{M})$ is bounded). By assumption on $\mathcal{M}$, the finitely many non-zero $h^q(\mathcal{M})$'s are in $\mathbf{qgr}(A)$. So equation (12) implies that for $i-j \gg 0$, the term E_2^{pq} is concentrated on the line $p=0$. So the spectral sequence collapses and gives

$$\mathrm{Hom}_{\mathbf{QGr}(A)}(\mathcal{O}, h^q(\mathcal{M})(i-j)) \cong \mathrm{Ext}_{\mathbf{QGr}(A)}^q(\mathcal{O}, \mathcal{M}(i-j)) \quad (13)$$

for $i-j \gg 0$ and each q .

Now observe that the isomorphism (13) also holds for $q \gg 0$, simply because both sides are then zero. For the left hand side, this holds because $h(\mathcal{M})$ is bounded. For the right hand side, use that $h(\mathcal{M})$ is bounded and that $\mathbf{qgr}(A)$ has cohomological dimension at most $d-1$ by [1, prop. 7.10(3)].

So setting q equal to j , the isomorphism (13) holds for $j \gg 0$, and for other values of j I can force $i-j \gg 0$ by picking $i \gg 0$, and then the isomorphism also holds. That is,

$$\mathrm{Hom}_{\mathbf{QGr}(A)}(\mathcal{O}, h^j(\mathcal{M})(i-j)) \cong \mathrm{Ext}_{\mathbf{QGr}(A)}^j(\mathcal{O}, \mathcal{M}(i-j))$$

for $i \gg 0$ and each j , proving the lemma. $\square$

5. PERIODIC INJECTIVE RESOLUTIONS

This section shows how the BGG correspondence can be used to understand periodicity of certain injective resolutions over exterior algebras as a geometric phenomenon.

I also show an analogous non-commutative example with much more complicated behaviour, due to the more intricate nature of non-commutative geometry.

The commutative case. The periodicity in question was discovered by Eisenbud in [5, thm. 2.2]. Let E be the exterior algebra $\bigwedge(Y_1, \dots, Y_d)$, and recall that $\mathbf{gr}(E)$ is the category of finitely generated graded E -left-modules.

Theorem 5.1 (Eisenbud). *Let M in $\mathbf{gr}(E)$ be without injective direct summands, and suppose that the Bass numbers*

$$\mu^i(M) = \dim_k \operatorname{Ext}_E^i(k, M)$$

are bounded for $i \geq 0$.

Then the minimal injective resolution I of M is periodic with period one in the following sense: Up to isomorphism, I^i is $I^0(i)$ and ∂_I^{i+1} is $\partial_I^1(i)$.

In other words, up to isomorphism and degree shift, all the I^i and all the ∂_I^i are the same. (In fact, Eisenbud worked with minimal free resolutions, but using Matlis duality on his result gives theorem 5.1.)

This phenomenon can be understood geometrically in a very simple way, using the BGG correspondence: The module M can be translated to a geometric object on $\mathbb{P}^{d-1}$, and since the Bass numbers of M are bounded, this object turns out to have zero dimensional support. Therefore the object is stable under twisting, that is, tensoring by $\mathcal{O}_{\mathbb{P}^{d-1}}(1)$, and translating back, this gives that M is its own first syzygy, and periodicity of the minimal injective resolution follows.

In more detail, let A be the polynomial algebra $k[X_1, \dots, X_d]$ so I am in the situation of example 3.2. In particular, $A^!$ is the exterior algebra $E = \bigwedge(Y_1, \dots, Y_d)$, and $\mathbf{QGr}(A)$ is equivalent to $\mathbf{QCoh}(\mathbb{P}^{d-1})$. Let M be in $\mathbf{gr}(E)$, and suppose that the Bass numbers

$$\mu^i(M) = \dim_k \operatorname{Ext}_E^i(k, M)$$

are bounded for $i \geq 0$.

The BGG correspondence associates to M the object $\mathcal{M} = \varphi(M)$ of $\mathbf{D}(\mathbf{QCoh} \mathbb{P}^{d-1})$. In fact, $\mathcal{M}$ is even in $\mathbf{D}^b(\mathbf{QCoh} \mathbb{P}^{d-1})$ by lemma 4.3, so only finitely many of the cohomologies $h^\ell(\mathcal{M})$ are non-zero, and each $h^\ell(\mathcal{M})$ is coherent.

For $i \geq 1$ I have

$$\begin{aligned}
\mu^i(M) &= \dim_k \operatorname{Ext}_E^i(k, M) \\
&\stackrel{(a)}{=} \sum_j \dim_k \operatorname{Ext}_{\operatorname{Gr}(E)}^i(k, M(-i+j)) \\
&\stackrel{(b)}{=} \sum_j \dim_k \operatorname{Ext}_{\operatorname{QCoh}(\mathbb{P}^{d-1})}^j(\mathcal{O}_{\mathbb{P}^{d-1}}, \mathcal{M}(i-j)) \\
&= (*),
\end{aligned}$$

where in (a), I am being clever by using the degree shift $-i+j$ instead of simply j , and where (b) is by lemma 4.2. And for $i \gg 0$ I have

$$(*) = \sum_j \dim_k \operatorname{Hom}_{\operatorname{QCoh}(\mathbb{P}^{d-1})}(\mathcal{O}_{\mathbb{P}^{d-1}}, h^j(\mathcal{M})(i-j)) \quad (14)$$

by lemma 4.4.

So if $\mu^i(M)$ is bounded for $i \geq 0$, then each summand in equation (14) is bounded for $i \gg 0$. That is,

$$\dim_k \operatorname{Hom}_{\operatorname{QCoh}(\mathbb{P}^{d-1})}(\mathcal{O}_{\mathbb{P}^{d-1}}, h^j(\mathcal{M})(\ell)) \quad (15)$$

is bounded for each j and $\ell \gg 0$. However, this is now a geometric statement: For $\ell \gg 0$, the polynomial growth rate of the numbers in equation (15) equals the dimension of the support of $h^j(\mathcal{M})$ on $\mathbb{P}^{d-1}$, as follows from [8, thm. I.7.5]. So it follows that each of the finitely many non-zero $h^j(\mathcal{M})$ has zero dimensional support; in other words, the support is a finite collection of points.

Now suppose that the ground field k is infinite. Then it is possible to pick a hyperplane H in $\mathbb{P}^{d-1}$ which is disjoint from the support of each $h^j(\mathcal{M})$. To H corresponds an injection $\mathcal{O}_{\mathbb{P}^{d-1}}(1) \hookrightarrow \mathcal{O}_{\mathbb{P}^{d-1}}$ which is an isomorphism away from H . Tensoring over $\mathcal{O}_{\mathbb{P}^{d-1}}$ with $\mathcal{M}$ gives a morphism $\mathcal{M} \otimes \mathcal{O}_{\mathbb{P}^{d-1}}(1) \xrightarrow{\mu} \mathcal{M} \otimes \mathcal{O}_{\mathbb{P}^{d-1}}$ and $h^j(\mu)$ is $h^j(\mathcal{M}) \otimes \mathcal{O}_{\mathbb{P}^{d-1}}(1) \longrightarrow h^j(\mathcal{M}) \otimes \mathcal{O}_{\mathbb{P}^{d-1}}$. However, this is an isomorphism for each j because $\mathcal{O}_{\mathbb{P}^{d-1}}(1) \hookrightarrow \mathcal{O}_{\mathbb{P}^{d-1}}$ is an isomorphism away from H and hence an isomorphism on the support of each $h^j(\mathcal{M})$. So μ is an isomorphism in $\operatorname{D}(\operatorname{QCoh} \mathbb{P}^{d-1})$, proving

$$\mathcal{M}(1) \cong \mathcal{M}.$$

Under the BGG correspondence this gives $\gamma(\mathcal{M}(1)) \cong \gamma(\mathcal{M})$, and using $\gamma(\mathcal{M}) = \gamma\varphi(M) \cong M$ and lemma 3.4(ii) this can be rearranged to

$$\Sigma M \cong M(1) \quad (16)$$

in $\overline{\operatorname{Gr}}(E)$.

In $\overline{\operatorname{Gr}}(E)$, the suspension ΣM is computed as the first syzygy of M in an injective resolution, cf. remark 2.4. So equation (16) shows

that in $\overline{\mathrm{Gr}}(E)$, this first syzygy is just M itself, with a degree shift of one. It is possible to improve this with a few remarks: First, if M is without injective direct summands, then it is not hard to show that the isomorphism (16) lifts to hold in $\mathrm{Gr}(E)$, if ΣM is obtained as the first syzygy in a *minimal* injective resolution of M . Secondly, the assumption that k is infinite can be dropped using [7, prop. 2.5.8].

Iterating equation (16) now shows that in the minimal injective resolution I of M , the syzygy $\Sigma^i M$ is simply $M(i)$. Hence the module I^i must be $I^0(i)$, and the morphism ∂_I^{i+1} must be $\partial_I^1(i)$. So I have recovered theorem 5.1.

The non-commutative case. In the above argument, the minimal injective resolution is periodic with period one because points in $\mathbb{P}^{d-1}$ are invariant under twisting. It is known that this invariance breaks down when one passes to non-commutative analogues of $\mathbb{P}^{d-1}$.

Here the twist can move points, and it is possible to have orbits of length n , for any finite n , and orbits of infinite length. So it is obvious to expect that suitable non-commutative analogues of the above argument might give examples of algebras $A^\dagger$, analogous to E , and modules M where $\mu^i(M)$ is bounded for $i \geq 0$, and yet where the minimal injective resolution of M is periodic with period n , or aperiodic. Indeed, this turns out to hold.

Note that the following example of this behaviour is already known from [10]. But the present geometric view through the BGG correspondence is new.

Setup 5.2. Suppose that the ground field k is algebraically closed, and suppose that C is an elliptic curve over k with a line bundle $\mathcal{L}$ of degree d and an automorphism τ given by translation by a point of C . To these data, [10, sec. 8] associates a so-called Sklyanin algebra which satisfies the standing assumptions from setup 0.1. Let A be this algebra.

Observe that A is a non-commutative analogue of the polynomial algebra $k[X_1, \dots, X_d]$ and that hence, the Koszul dual $A^\dagger$ is a non-commutative analogue of the exterior algebra $\bigwedge(Y_1, \dots, Y_d)$.

Setup 5.3. The construction of A in [10, sec. 8] is so that C sits inside $\mathbb{P}(A_1^\dagger)$. So each point p on C is also a point in $\mathbb{P}(A_1^\dagger)$, that is, a one dimensional subspace of $A_1^\dagger$. This subspace has an annihilator $p^\perp$ in A_1 , and the graded A -left-module $P(p) = A/Ap^\perp$ is a so-called point module. That is, it is cyclic, and each graded piece in non-negative degrees is one dimensional.

Let me now write

$$\mathcal{M}(p) = \pi(P(p)).$$

This is an object of $\mathbf{qgr}(A)$, and I view it as a complex concentrated in cohomological degree zero. This complex is an object of $\mathbf{D}(\mathbf{QGr} A)$, so finally the BGG correspondence gives the object

$$M(p) = \gamma(\mathcal{M}(p))$$

in $\overline{\mathbf{Gr}}(A^!)$. In fact, $\mathcal{M}(p)$ viewed as an object of $\mathbf{D}(\mathbf{QGr} A)$ is in the subcategory $\mathbf{D}^b(\mathbf{QGr} A)$, so lemma 4.3 says that $M(p)$ is even in $\overline{\mathbf{gr}}(A^!)$.

Observe that $M(p)$ is only well-defined up to isomorphism in $\overline{\mathbf{Gr}}(A^!)$, so when looking at $M(p)$ as a graded $A^!$ -left-module, I can drop any injective direct summands, and so assume that $M(p)$ is without injective direct summands.

Let me start by pointing out the following property of the modules $M(p)$.

Proposition 5.4. *The Bass numbers $\mu^i(M(p))$ are bounded for $i \geq 0$.*

Proof. For $i \gg 0$ I have

$$\begin{aligned} \mu^i(M(p)) &= \dim_k \operatorname{Ext}_{A^!}^i(k, M(p)) \\ &\stackrel{(a)}{=} \sum_j \dim_k \operatorname{Ext}_{\mathbf{Gr}(A^!)}^i(k, M(p)(-i+j)) \\ &\stackrel{(b)}{=} \sum_j \dim_k \operatorname{Ext}_{\mathbf{QGr}(A)}^j(\mathcal{O}, \mathcal{M}(p)(i-j)) \\ &\stackrel{(c)}{=} \sum_j \dim_k \operatorname{Hom}_{\mathbf{QGr}(A)}(\mathcal{O}, h^j(\mathcal{M}(p))(i-j)) \\ &= (*), \end{aligned}$$

where in (a), I am being clever by using the degree shift $-i+j$ instead of j , where (b) is by lemma 4.2, and where (c) is by lemma 4.4. However, the complex $\mathcal{M}(p)$ is just the object $\mathcal{M}(p)$ placed in cohomological degree zero, so

$$(*) = \dim_k \operatorname{Hom}_{\mathbf{QGr}(A)}(\mathcal{O}, \mathcal{M}(p)(i)) = (**),$$

and since $\mathcal{M}(p)$ is $\pi(P(p))$ and i is large, this is

$$(**) = \dim_k P(p)_i = 1$$

by [1, thm. 8.1(1) and prop. 3.13(2)], because the algebra A is AS regular. $\square$

Now some computations with the $M(p)$'s.

Lemma 5.5. *The module $M(p)$ determines p .*

Proof. It is certainly true that $M(p)$ determines $\mathcal{M}(p) \cong \varphi(M(p))$. In turn, $\mathcal{M}(p)$ determines the tail $P(p)_{\geq n}$ for $n \gg 0$, because when viewing $\mathcal{M}(p)$ as an object of $\mathbf{qgr}(A)$, I have

$$P(p)_{\geq n} \cong \omega\pi(P(p))_{\geq n} = \omega(\mathcal{M}(p))_{\geq n} \quad (17)$$

for $n \gg 0$ by [1, thm. 8.1(1) and prop. 3.13(2)]. But $P(p)_{\geq n}$ determines p by [10, sec. 8], so $M(p)$ does too. $\square$

Lemma 5.6. *The modules $M(p)$ satisfy*

$$\Sigma(M(p)) \cong M(\tau^{2-d}p)(1)$$

in $\overline{\mathbf{Gr}}(A^1)$.

Proof. In [10, exam. 9.5] is proved

$$P(p)_{\geq 1}(1) \cong P(\tau^{2-d}p),$$

and applying π shows

$$\mathcal{M}(p)(1) \cong \mathcal{M}(\tau^{2-d}p)$$

because π only sees the tail of a module. Applying γ and lemma 3.4(ii), this can be rearranged to the lemma's isomorphism

$$\Sigma(M(p)) \cong M(\tau^{2-d}p)(1).$$

$\square$

Lemma 5.7. *If $\Sigma^i(M(p)) \cong M(q)(j)$ holds in $\overline{\mathbf{Gr}}(A^1)$ for some points p and q on C , then $i = j$.*

Proof. The lemma's isomorphism implies $\varphi(\Sigma^i(M(p))) \cong \varphi(M(q)(j))$, and using lemma 3.4(i) and $\varphi(M(p)) = \mathcal{M}(p)$, this becomes $\Sigma^i(\mathcal{M}(p)) \cong \Sigma^j(\mathcal{M}(q))(-j)$. Since the cohomologies of $\mathcal{M}(p)$ and $\mathcal{M}(q)$ are concentrated in cohomological degree zero, this is only possible with $i = j$. $\square$

Finally, these lemmas can be used as follows. If there is to be periodicity in the sense

$$\Sigma^i(M(p)) \cong M(p)(j) \quad (18)$$

in $\overline{\mathbf{Gr}}(A^1)$ for some i and j , then $i = j$ by lemma 5.7. On the other hand, $\Sigma^i(M(p)) \cong M(\tau^{(2-d)i}p)(i)$ holds by lemma 5.6. Substituting into equation (18) gives $M(\tau^{(2-d)i}p)(i) \cong M(p)(i)$, hence $M(\tau^{(2-d)i}p) \cong M(p)$, and as $M(p)$ determines p by lemma 5.5, this implies $\tau^{(2-d)i}(p) = p$.

Conversely, $\tau^{(2-d)i}(p) = p$ gives

$$\Sigma^i(M(p)) \cong M(\tau^{(2-d)i}p)(i) \cong M(p)(i)$$

in $\overline{\text{Gr}}(A^!)$.

Summing up, if d , τ and p are so that $\tau^{(2-d)i}(p) \neq p$ for $i = 1, \dots, n-1$ but $\tau^{(2-d)n}(p) = p$, then in $\overline{\text{Gr}}(A^!)$ the suspension $\Sigma^i(M(p))$ is not a degree shift of $M(p)$ for $i = 1, \dots, n-1$, but $\Sigma^n(M(p))$ is $M(p)(n)$.

And if d , τ and p are so that $\tau^{(2-d)i}(p) \neq p$ for $i \geq 1$, then in $\overline{\text{Gr}}(A^!)$ the suspension $\Sigma^i(M(p))$ is not a degree shift of $M(p)$ for $i \geq 1$.

Using that $M(p)$ contains no injective direct summands, this easily lifts to give the same result in $\text{Gr}(A^!)$ for syzygies in *minimal* injective resolutions. So I get the following example which shows the promised contrast to theorem 5.1 with respect to periodicity of minimal injective resolutions.

Example 5.8. (1) Let d , τ and p be so that $\tau^{(2-d)i}(p) \neq p$ for $i = 1, \dots, n-1$ but $\tau^{(2-d)n}(p) = p$.

Then the minimal injective resolution I of $M(p)$ is periodic with period n , in the sense that in the resolution, the i 'th syzygy $\Sigma^i(M(p))$ is not isomorphic to a degree shift of $M(p)$ for $i = 1, \dots, n-1$, but the n 'th syzygy $\Sigma^n(M(p))$ is isomorphic to $M(p)(n)$.

Hence up to isomorphism, I^n is $I^0(n)$ and ∂_I^{n+1} is $\partial_I^1(n)$, while the same is not true with any smaller value of n .

(2) Let d , τ and p be so that $\tau^{(2-d)i}(p) \neq p$ for $i \geq 1$.

Then the minimal injective resolution I of $M(p)$ is aperiodic, in the sense that in the resolution, no syzygy $\Sigma^i(M(p))$ is a degree shift of $M(p)$ for $i \geq 1$.

Acknowledgement. The diagrams were typeset with Paul Taylor's `diagrams.tex`.
